

# Code optimization

Advanced Compiler Construction  
Michel Schinz – 2025-03-27

# Optimization

Goal: rewrite the program to a new one that is:

- behaviorally equivalent to the original one,
- better in some respect – e.g. faster, smaller, more energy-efficient, etc.

Optimizations can be broadly split in two classes:

- **machine-independent optimizations** are high-level and do not depend on the target architecture,
- **machine-dependent optimizations** are low-level and depend on the target architecture.

This lesson: machine-independent, rewriting optimizations.

# IRs and optimizations

# The importance of IRs

Intermediate representations (IRs) have a dramatic impact on optimizations, which generally work in two steps:

1. the program is analyzed to find optimization opportunities,
2. the program is rewritten based on the analysis.

The IR should make both steps as easy as possible.

# Case 1: constant propagation

Consider the following program fragment in some imaginary IR:

$x \leftarrow 7$

...

Question: can all occurrences of  $x$  be replaced by 7?

Answer: it depends on the IR:

- if it allows multiple assignments, no (further data-flow analyses are required),
- if it disallows multiple assignment, yes!

# Other simple optimizations

Multiple assignments make most simple optimizations hard:

- *common subexpression elimination*, which consists in avoiding the repeated evaluation of expressions,
- (simple) *dead code elimination*, which consists in removing assignments to variables whose value is not used later,
- etc.

Common problem: analyses are required to distinguish the various “versions” of a variable that appear in the program.

Conclusion: a good IR should not allow multiple assignments to a variable!

# Case 2: inlining

*Inlining* replaces a call to a function by a copy of the body of that function, with parameters replaced by the actual arguments.

The IR used also has a dramatic impact on it, as we can see if we try to do inlining on the AST – which might look sensible at first.

# Naïve inlining: problem #1

```
(def print/ret (fun (x) (int-print x) x))  
(def twice (fun (y) (+ y y)))  
(def f (fun (z) (twice (print/ret z))))
```

incorrect inlining  
of twice in f

```
(def f (fun (z)  
          (+ (print/ret z)  
             (print/ret z))))
```

z is  
printed  
twice!

Possible solution: bind actual parameters to variables (using a `let`) to ensure that they are evaluated *at most* once.

# Naïve inlining: problem #2

```
(def first (fun (x y) x))  
(def print/ret  
  (fun (z) (first z (int-print z))))
```

incorrect inlining of  
first in print/ret

```
(def print/ret (fun (z) z))
```

z isn't  
printed at all!

Possible solution: bind actual parameters to variables (using a `let`) to ensure that they are evaluated *at least* once.

# Easy inlining

Common solution:

- bind actual arguments to variables before using them in the body of the inlined function.

However:

- the IR can also avoid the problem by ensuring that actual parameters are always atoms (variables/constants).

Conclusion:

- a good IR should only allow atomic arguments to functions.

# IR comparison

Conclusion:

- standard RTL/CFG is:
  - bad as its variables are mutable, but
  - good as it allows only atoms as function arguments,
- RTL/CFG in SSA form and CPS/L<sub>3</sub> are:
  - good as their variables are immutable,
  - good as they only allow atoms as function arguments.

# Simple CPS/L<sub>3</sub> optimizations

# Rewriting optimizations

The rewriting optimizations for CPS/L<sub>3</sub> are specified as a set of rewriting rules of the form  $T \rightsquigarrow_{\text{opt}} T'$ .

These rules rewrite a CPS/L<sub>3</sub> term  $T$  to an equivalent – but hopefully more efficient – term  $T'$ .

# (Non-)shrinking rules

We can distinguish two classes of rewriting rules:

1. **shrinking rules** rewrite a term to an equivalent but smaller one, and can be applied at will,
2. **non-shrinking rules** rewrite a term to an equivalent but potentially larger one, and must be applied carefully.

Except for inlining, all optimizations we will see are shrinking.

# Optimization contexts

Rewriting rules can only be applied in specific locations. For example, it would be incorrect to try to rewrite the parameter list of a function.

We express this constraint by specifying all the **contexts** in which it is valid to perform a rewrite, where a context is a term with a single **hole** denoted by  $\square$ .

The hole of a context  $C$  can be plugged with a term  $T$ , an operation written as  $C[T]$ .

For example, if  $C$  is  $(\text{if } \square \text{ ct cf})$ , then  $C[(= x y)]$  is

$(\text{if } (= x y) \text{ ct cf})$ .

# Optimization contexts

$C_{\text{opt}} ::= \square$

|  $(\text{let}_p ((n (p \ a_1 \dots))) \ C_{\text{opt}})$

|  $(\text{let}_c ((c_1 \ e_1) \dots (c_i (\text{cnt} \ (n_{i,1} \dots) \ C_{\text{opt}})) \dots (c_k \ e_k)) \ e)$

|  $(\text{let}_c ((c_1 \ e_1) \dots) \ C_{\text{opt}})$

|  $(\text{let}_f ((f_1 \ e_1) \dots (f_i (\text{fun} \ (n_{i,1} \dots) \ C_{\text{opt}})) \dots (f_k \ e_k)) \ e)$

|  $(\text{let}_f ((f_1 \ e_1) \dots) \ C_{\text{opt}})$

# Optimization relation

By combining the optimization rewriting rules – presented later – and the optimization contexts, it is possible to specify the optimization relation  $\Rightarrow_{\text{opt}}$  that rewrites a term to an optimized version:

$$C_{\text{opt}}[T] \Rightarrow_{\text{opt}} C_{\text{opt}}[T'] \text{ where } T \rightsquigarrow_{\text{opt}} T'$$

# Dead code elimination

$(\text{let}_p ((n (p a_1 \dots))) e)$

$\rightsquigarrow_{\text{opt}} e$

[when  $n$  is not free in  $e$  and  $p \notin \{\text{byte-read}, \text{byte-write}, \text{block-set!}\}$ ]

$(\text{let}_f ((n_1 f_1) \dots (n_{i-1} f_{i-1}) (n_i f_i) (n_{i+1} f_{i+1}) \dots (n_k f_k)) e)$

$\rightsquigarrow_{\text{opt}} (\text{let}_f ((n_1 f_1) \dots (n_{i-1} f_{i-1}) (n_{i+1} f_{i+1}) \dots (n_k f_k)) e)$

[when  $n_i$  is not free in  $\{f_1, \dots, f_{i-1}, f_{i+1}, \dots, f_k, e\}$ ]

The rule for continuations is similar to the one for functions.

# Dead code elimination

Limitation:

Does not eliminate dead, mutually-recursive functions.

Solution:

- start from the main expression of the program, and
- identify all functions transitively reachable from it.

All unreachable functions are dead.

# CSE

$$\begin{aligned} & (\text{let}_p \ ((n_1 \ (+ \ a_1 \ a_2))) \\ & \quad C_{\text{opt}}[(\text{let}_p \ ((n_2 \ (+ \ a_1 \ a_2))) \ e)]) \\ & \rightsquigarrow_{\text{opt}} (\text{let}_p \ ((n_1 \ (+ \ a_1 \ a_2))) \ C_{\text{opt}}[e\{n_2 \rightarrow n_1\}]) \end{aligned}$$
$$\begin{aligned} & (\text{let}_p \ ((n_1 \ (- \ a_1 \ a_2))) \\ & \quad C_{\text{opt}}[(\text{let}_p \ ((n_2 \ (- \ a_1 \ a_2))) \ e)]) \\ & \rightsquigarrow_{\text{opt}} (\text{let}_p \ ((n_1 \ (- \ a_1 \ a_2))) \ C_{\text{opt}}[e\{n_2 \rightarrow n_1\}]) \end{aligned}$$

etc.

# CSE

Limitation:

Some opportunities are missed because of scoping.

Example:

Common subexpression (+ y z) is not optimized:

```
(letc ((c1 (cnt ()  
              (letp ((x1 (+ y z))  
                    ...)))  
      (c2 (cnt ()  
            (letp ((x2 (+ y z))  
                    ...))))  
  ...)
```

# $\eta$ -reduction

$$\begin{aligned} & (\text{let}_c \ ((c_1 \ e_1) \dots \\ & \quad (c_i \ (\text{cnt} \ (n_1 \dots) \ (\text{app}_c \ d \ n_1 \dots))) \dots \\ & \quad (c_k \ e_k)) \\ & \ e) \\ & \rightsquigarrow_{\text{opt}} (\text{let}_c \ ((c_1 \ e_1\{c_i \rightarrow d\}) \dots (c_k \ e_k\{c_i \rightarrow d\})) \ e\{c_i \rightarrow d\}) \end{aligned}$$
$$\begin{aligned} & (\text{let}_f \ ((n_1 \ f_1) \dots \\ & \quad (n_i \ (\text{fun} \ (c \ m_1 \dots) \ (\text{app}_f \ g \ c \ m_1 \dots)) \dots \\ & \quad (n_k \ f_k)) \\ & \ e) \\ & \rightsquigarrow_{\text{opt}} (\text{let}_f \ ((n_1 \ f_1\{n_i \rightarrow g\}) \dots (n_k \ f_k\{n_i \rightarrow g\})) \ e\{n_i \rightarrow g\}) \end{aligned}$$

[when  $g \notin \{m_1, \dots\}$ ]

# Constant folding (1)

$(\text{let}_p ((n (+ l_1 l_2))) e)$

$\rightsquigarrow_{\text{opt}} e\{n \rightarrow (l_1 + l_2)\}$

[when  $l_1$  and  $l_2$  are integer literals]

$(\text{let}_p ((n (- l_1 l_2))) e)$

$\rightsquigarrow_{\text{opt}} e\{n \rightarrow (l_1 - l_2)\}$

[when  $l_1$  and  $l_2$  are integer literals]

$(\text{let}_p ((n (* l_1 l_2))) e)$

$\rightsquigarrow_{\text{opt}} e\{n \rightarrow (l_1 \times l_2)\}$

[when  $l_1$  and  $l_2$  are integer literals]

etc.

# Constant folding (2)

$(\text{if } (= a a) c_t c_f)$   
 $\rightsquigarrow_{\text{opt}} (\text{app}_c c_t)$

$(\text{if } (< a a) c_t c_f)$   
 $\rightsquigarrow_{\text{opt}} (\text{app}_c c_f)$

etc.

# Neutral/absorbing elements

$(\text{let}_p ((n (* 1 a))) e)$

$\rightsquigarrow_{\text{opt}} e\{n \rightarrow a\}$

$(\text{let}_p ((n (* a 1))) e)$

$\rightsquigarrow_{\text{opt}} e\{n \rightarrow a\}$

$(\text{let}_p ((n (* 0 a))) e)$

$\rightsquigarrow_{\text{opt}} e\{n \rightarrow 0\}$

$(\text{let}_p ((n (* a 0))) e)$

$\rightsquigarrow_{\text{opt}} e\{n \rightarrow 0\}$

etc.

# Block primitives

```
(letp ((b (block-alloc t s)))  
  Copt[(letp ((u (block-set! b i a)))  
    C'opt[(letp ((n (block-get b i))) e)]]])  
⇒opt (letp ((b (block-alloc t s)))  
  Copt[(letp ((u (block-set! b i a)))  
    C'opt[e{n→a}]]])
```

*[when tag t identifies a block that is not modified after initialization, e.g. a closure block]*

# Exercise

CPS/L<sub>3</sub> contains the following block primitives:

- `block-alloc` tag size
- `block-tag` block
- `block-size` block
- `block-get` block index
- `block-set!` block index value

Informally describe three rewriting optimizations that could be performed on these primitives, and in which conditions they could be performed.

**CPS/L<sub>3</sub> inlining**

# (Non-)shrinking inlining

We can distinguish two kinds of inlining:

1. **shrinking inlining**, for functions/continuations that are applied exactly once,
2. **non-shrinking inlining**, for other functions/continuations.

Shrinking inlining can be applied at will, non-shrinking cannot.

# Shrinking Inlining

$$\begin{aligned} & (\text{let}_f \ ((f_1 \ e_1) \dots (f_{i-1} \ e_{i-1}) (f_i \ (\text{fun} \ (c_i \ n_{i,1} \ \dots) \ e_i)) (f_{i+1} \ e_{i+1}) \dots (f_k \ e_k)) \\ & \quad C_{\text{opt}}[(\text{app}_f \ f_i \ c \ m_1 \ \dots)]) \\ & \rightsquigarrow_{\text{opt}} (\text{let}_f \ ((f_1 \ e_1) \dots (f_{i-1} \ e_{i-1}) (f_{i+1} \ e_{i+1}) \dots (f_k \ e_k)) \\ & \quad C_{\text{opt}}[e_i\{c_i \rightarrow c\}\{n_{i,1} \rightarrow m_1\}\dots]) \\ & \text{[when } f_i \text{ is not free in } C_{\text{opt}}, e_1, \dots, e_n] \end{aligned}$$

Similar rules exist to do the inlining inside of the body of one of the functions.

# Non-shrinking Inlining

In non-shrinking inlining, fresh versions of bound names should be created to preserve their global uniqueness:

$$\begin{aligned} & (\text{let}_f \dots (f_i (\text{fun } (c_i \ n_{i,1} \dots) e_i)) \dots) \\ & \quad C_{\text{opt}}[(\text{app}_f \ f_i \ c \ m_1 \dots)] \\ \rightsquigarrow_{\text{opt}} & (\text{let}_f \dots (f_i (\text{fun } (c_i \ n_{i,1} \dots) e_i)) \dots) \\ & \quad C_{\text{opt}}[e_i\{c_i \rightarrow c\}\{n_{i,1} \rightarrow m_1\} \dots] \end{aligned}$$

Similar rules exist to do the inlining inside of the body of one of the functions.

# Inlining heuristics (1)

Heuristics must be used to decide when to perform non-shrinking inlining.

They typically combine several factors, like:

- the size of the candidate function – smaller ones should be inlined more eagerly than bigger ones,
- the number of times the candidate is called in the whole program – a function called only a few times should be inlined,

*(continued on next slide)*

# Inlining heuristics (2)

- the nature of the candidate – not much gain can be expected from the inlining of a recursive function,
- the kind of arguments passed to the candidate, and/or the way these are used in the candidate – constant arguments could lead to further reductions in the inlined candidate, especially if it combines them with other constants,
- etc.

# Exercise

Imagine an imperative intermediate language equipped with a `return` statement to return from the current function to its caller.

1. Describe the problem that would appear when inlining a function containing such a `return` statement.
2. Explain how a `return` statement could be encoded in CPS/L<sub>3</sub> and why such an encoding would not suffer from the above problem.

**CPS/L<sub>3</sub>**

**“contifification”**

# Contification

**Contification:** transforms functions into continuations.

Interesting optimization as it transforms functions, which are expensive (closures) into continuations, which are cheap.

# Contification example

Example: the `loop` function in the  $L_3$  example below can be contified, leading to efficient compiled code.

```
(def fact
  (fun (x)
    (rec loop ((i 1) (r 1))
      (if (> i x)
        r
        (loop (+ i 1) (* r i))))))
```

# Contifiability

A CPS/ $L_3$  function is contifiable if and only if it always returns to the same location – because then it does not need a return continuation.

- Non-recursive case: true iff that function is only used in  $\text{app}_f$  nodes, in function position, and always passed the same return continuation.
- Recursive case: slightly more involved – see later.

# Non-recursive contification

The contification of the non-recursive function  $f$  is given by:

$$\begin{aligned} & (\text{let}_f ((f (\text{fun } (c \ a_1 \ \dots) \ e))) \\ & \quad C_{\text{opt}}[C'_{\text{opt}}[(\text{app}_f \ f \ c_0 \ n_{1,1} \ \dots), (\text{app}_f \ f \ c_0 \ n_{2,1} \ \dots), \dots]]) \\ & \rightsquigarrow_{\text{opt}} C_{\text{opt}}[(\text{let}_c ((m (\text{cnt } (a_1 \ \dots) \ e\{c \rightarrow c_0\}))) \\ & \quad \quad C'_{\text{opt}}[(\text{app}_c \ m \ n_{1,1} \ \dots), (\text{app}_c \ m \ n_{2,1} \ \dots), \dots]])] \end{aligned}$$

where:

- $f$  does not appear free in  $C_{\text{opt}}$  or  $C'_{\text{opt}}$ ,
- $C'_{\text{opt}}$  is the smallest (multi-hole) context enclosing all applications of  $f$ ,
- $c_0$  is the (single) return continuation that is passed to function  $f$ .

# Recursive contifiability

A set of mutually-recursive functions  $F = \{ f_1, \dots, f_n \}$  is contifiable – which we write  $\text{Cnt}(F)$  – if and only if every function in  $F$  is always used in one of the following two ways:

1. applied to a common return continuation, or
2. called in tail position by a function in  $F$ .

Intuitively, this ensures that all functions in  $F$  eventually return through the common continuation.

# Example

As an example, functions `even` and `odd` in the CPS/ $L_3$  translation of the following  $L_3$  term are contifiable:

```
(letrec
  ((even (fun (x)
            (if (= 0 x) #t (odd (- x 1)))))
   (odd (fun (x)
            (if (= 0 x) #f (even (- x 1)))))
  (even 12))
```

$\text{Cnt}(F = \{\text{even}, \text{odd}\})$  is satisfied since:

- the single use of `odd` is a tail call from `even`  $\in F$ ,
- `even` is tail-called from `odd`  $\in F$  and called with the continuation of the `letrec` statement – the common return continuation  $c_0$  for this example.

# Recursive contification

Given a set of mutually-recursive functions

$(\text{let}_f \ ((f_1\ e_1)\ (f_2\ e_2)\ \dots\ (f_n\ e_n))\ e)$

the condition  $\text{Cnt}(F)$  for some  $F \subseteq \{f_1, \dots, f_n\}$  can only be true if all the non tail calls to functions in  $F$  appear either:

- in the term  $e$ , or
- in the body of exactly one function  $f_i \notin F$ .

Therefore, two separate rewriting rules must be defined, one per case.

# Recursive contification #1

Case 1: all non tail calls to functions in  $F = \{ f_1, \dots, f_i \}$  appear in the body of the  $\text{let}_f$ ,  $\text{Cnt}(F)$  holds and  $c_0$  is the common return continuation:

$$\begin{aligned} & (\text{let}_f \ ((f_1 \ (\text{fun} \ (c_1 \ a_{1,1} \ \dots) \ e_1)) \ \dots \ (f_n \ \dots)) \\ & \quad C_{\text{opt}}[e]) \\ & \rightsquigarrow_{\text{opt}} (\text{let}_f \ ((f_{i+1} \ (\text{fun} \ (c_{i+1} \ a_{i+1,1} \ \dots) \ e_{i+1})) \ \dots \ (f_n \ \dots)) \\ & \quad C_{\text{opt}}[(\text{let}_c \ ((m_1 \ (\text{cnt} \ (a_{1,1} \ \dots) \\ & \quad \quad e_1^*\{c_1 \rightarrow c_0\})) \ \dots) \\ & \quad \quad e^*)])) \end{aligned}$$

where  $f_1, \dots, f_i$  do not appear free in  $C_{\text{opt}}$  and  $e$  is minimal.

Note: the term  $t^*$  is  $t$  with all applications of contified functions transformed to continuation applications.

# Recursive contification #2

Case 2: all non tail calls to functions in  $F = \{ f_1, \dots, f_i \}$  appear in the body of the function  $f_n$ ,  $\text{Cnt}(F)$  holds and  $c_0$  is the common return continuation:

$$\begin{aligned} & (\text{let}_f \ ((f_1 \ (\text{fun} \ (c_1 \ a_{1,1} \ \dots) \ e_1)) \ \dots \\ & \quad (f_n \ (\text{fun} \ (c_n \ a_{n,1} \ \dots) \ C_{\text{opt}}[e_n])) \ e) \\ & \rightsquigarrow_{\text{opt}} (\text{let}_f \ ((f_{i+1} \ (\text{fun} \ (c_{i+1} \ a_{i+1,1} \ \dots) \ e_{i+1})) \ \dots \\ & \quad (f_n \ (\text{fun} \ (c_n \ a_{n,1} \ \dots) \\ & \quad \quad C_{\text{opt}}[(\text{let}_c \ ((m_1 \ (\text{cnt} \ (a_{1,1} \ \dots) \\ & \quad \quad \quad e_1^* \{c_1 \rightarrow c_0\})) \ \dots) \\ & \quad \quad \quad e_n^*] \ \dots) \ e) \end{aligned}$$

where  $f_1, \dots, f_i$  do not appear free in  $C_{\text{opt}}$  and  $e_n$  is minimal.

# Contifiable subsets

Given a  $\text{let}_f$  term defining a set of functions  $F = \{ f_1, \dots, f_n \}$ , the subsets of  $F$  of potentially contifiable functions are obtained by:

1. building the tail-call graph of its functions, identifying the functions that call each-other in tail position,
2. extracting the strongly-connected components of that graph.

A given set of strongly-connected functions  $F_i \subseteq F$  is then either contifiable together, i.e.  $\text{Cnt}(F_i)$ , or not contifiable at all – i.e. none of its subsets of functions are contifiable.
